(57) **ABSTRACT**

An image capturing method includes: continuously generating, using a processor, one or more OFF images in which the subject is captured with the illumination turned OFF, for a first number of times; continuously generating, using the processor, ON images in which the subject is captured with the illumination turned ON, for a second number of times; continuously generating, using the processor, one or more OFF images in which the subject is captured with the illumination turned OFF, for the first number of times; computing, using the processor, a difference image between each of the generated ON images and the OFF image corresponding to the ON image among the generated OFF images; and integrating, using the processor, the computed difference images.

IMAGE CAPTURING METHOD AND IMAGE CAPTURING APPARATUS FOR ILLUMINATING SUBJECT

CROSS-REFERENCE TO RELATED APPLICATION

This application is based upon and claims the benefit of priority of the prior Japanese Patent Application No. 2013-012688, filed on Jan. 25, 2013, the entire contents of which are incorporated herein by reference.

FIELD

The embodiments discussed herein are related to an image capturing method, an image capturing apparatus, and an image capturing program.

BACKGROUND

Various authentication technologies such as biometric authentication or gesture authentication have been known. In the biometric authentication, for example, there are cases where the authentication rate declines because the similarity between two images declines when the intensities of external light differs between capturing a registered image and capturing a matching image. Disclosed as an example of a technology for reducing the influence of external light is an image processing method for acquiring a difference between an OFF image captured during an OFF state in which the illumination is turned OFF and an ON image captured during an ON state in which the illumination is turned ON. The image processing method aims to acquire an image that does not include external light but illumination light by computing the difference between an OFF image captured with only the external light and an ON image captured with the external light and illumination light.

However, when the external light is strong, the pixel values for the portion illuminated with the external light within the area captured by the camera saturate at the upper boundary, and a phenomenon called saturation is thus produced in which such a portion becomes completely white. Therefore, when the difference between the OFF image and the ON image is simply acquired, the authentication ratio may remain low because the characteristics of the region to be biometrically authenticated are lost due to the saturation.

As an example of a technology for solving saturation, Japanese Laid-open Patent Publication No. 2008-90412, for example, discloses an image generating method for dividing an image capturing process into sub-steps based on the intensities of external light, alternately capturing OFF images and ON images, and integrating differences between respective pairs of the OFF image and ON image. This image generating method aims to acquire an image in which the influence of saturation is reduced by reducing the length of the exposure time during capturing of the images to reduce the amount of incident light and by integrating the captured difference images.

However, such a technology has a disadvantage that the time for capturing images is extended as explained below.

To explain, in the image generation method mentioned above, OFF images and ON images are captured alternately. When OFF images and ON images are captured alternately, the illumination is switched every time an OFF image or an ON image is to be captured. In other words, the illumination is switched from ON to OFF every time an OFF image is to be captured, and the illumination is switched from

2

OFF to ON every time an ON image is to be captured. Because images captured during the process of switching the illumination are captured without the illumination not completely turned OFF or completely turned ON, and such images could be a cause for reducing authentication accuracy, it is preferable not to use the images in the authentication. Because capturing operation is withheld until the illumination is switched OFF or ON every time an OFF image or an ON image is to be captured, the image capturing time is extended.

SUMMARY

According to an aspect of an embodiment, an image capturing method is executed by an image capturing apparatus including an illumination that illuminates a subject. The image capturing method includes: continuously generating, using a processor, one or more OFF images in which the subject is captured with the illumination turned OFF, for a first number of times; continuously generating, using the processor, ON images in which the subject is captured with the illumination turned ON, for a second number of times; continuously generating, using the processor, one or more OFF images in which the subject is captured with the illumination turned OFF, for the first number of times; computing, using the processor, a difference image between each of the generated ON images and the OFF image corresponding to the ON image among the generated OFF images; and integrating, using the processor, the computed difference images.

The object and advantages of the invention will be realized and attained by means of the elements and combinations particularly pointed out in the claims.

It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory and are not restrictive of the invention, as claimed.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a block diagram illustrating functional configurations of apparatuses included in a gesture authentication system according to a first embodiment of the present invention;

FIG. 2 is a schematic of an example of an image capturing sequence;

FIG. 3 is a schematic of another example of the image capturing sequence;

FIG. 4 is a schematic of another example of the image capturing sequence;

FIG. 5 is a schematic of another example of the image capturing sequence;

FIG. 6 is a schematic of an example of a relation between time and a variation level;

FIG. 7 is a flowchart illustrating an authenticating process according to the first embodiment;

FIG. 8 is a flowchart illustrating a divisor determining process according to the first embodiment;

FIG. 9 is a flowchart illustrating an image capturing process according to the first embodiment;

FIG. 10 is a block diagram illustrating functional configurations of apparatuses included in a face authentication system according to a second embodiment of the present invention;

FIG. 11 is a flowchart illustrating a registration process according to the second embodiment;

FIG. 12 is a flowchart illustrating an authenticating process according to the second embodiment;

FIG. 13 is a block diagram illustrating functional configurations of apparatuses included in a material determining system according to a third embodiment of the present invention;

FIG. 14 is a schematic of an example of an image capturing sequence;

FIG. 15 is a schematic of an example of information in which an output current is associated with a divisor;

FIG. 16 is a graph illustrating an example of a relation between a wavelength and reflectance of different materials;

FIG. 17 is a flowchart illustrating a determining process according to the third embodiment;

FIG. 18 is a flowchart illustrating a divisor determining process according to the third embodiment;

FIG. 19 is a flowchart illustrating an image capturing process according to the third embodiment;

FIG. 20 is a flowchart illustrating an example of a divisor determining process;

FIG. 21 is a schematic of an example of an image capturing sequence; and

FIG. 22 is a schematic for explaining an example of a computer for executing an image capturing program according to the first to the third embodiments.

DESCRIPTION OF EMBODIMENTS

Preferred embodiments of the present invention will be explained with reference to accompanying drawings. The embodiments are not intended to limit the technology according to the invention in any way. These embodiments may also be combined in any way within an extent not making any process contradictory.

[a] First Embodiment

FIG. 1 is a block diagram illustrating functional configurations of apparatuses included in a gesture authentication system according to a first embodiment of the present invention. This gesture authentication system 10 authenticates a gesture such as a bodily gesture or a hand gesture of a person, by using a difference image between an OFF image captured during an OFF state in which the illumination is turned OFF and an ON image captured during an ON state in which the illumination is turned ON. In the first embodiment, it is assumed that, as an example, the result of a gesture authentication output from an authentication apparatus 12 is used in operating a channel of a television receiver not illustrated. Alternatively, the gesture authentication result may be used as a human-machine interface of a personal computer or the like.

As illustrated in FIG. 1, the gesture authentication system 10 includes an image capturing apparatus 11 and the authentication apparatus 12. Illustrated in FIG. 1 is an example in which the image capturing apparatus 11 is provided in singularity to the gesture authentication system 10. Alternatively, the image capturing apparatus 11 may be provided in plurality.

Configuration of Image Capturing Apparatus 11

To begin with, a functional configuration of the image capturing apparatus 11 according to the first embodiment will be explained. As illustrated in FIG. 1, the image capturing apparatus 11 includes a sensor unit 11a, an illumination unit 11b, an image sensor 11c, a communicating unit 11d, an image storage unit 11e, and an image capturing control unit 11f. The image capturing apparatus 11 may also include various functional units provided to a camera, such as an optical lens or an optical filter, in addition to the functional units illustrated in FIG. 1.

Among these functional units, the sensor unit 11a is a device for detecting a user of the television receiver. As a

possible implementation of the sensor unit 11a, a human detection sensor that detects a person with visible light, infrared, ultrasonic waves, or temperature may be used. The sensor unit 11a monitors, for example, a predetermined viewing area, e.g., an area within a radius of 5 meters, from the display surface of the television receiver. When the sensor unit 11a detects a user in the viewing area of the television receiver, the sensor unit 11a notifies the image capturing control unit 11f, which will be described later, of the position of the user in the viewing area.

The illumination unit 11b is a light source that emits illuminating light. As a possible implementation of the illumination unit 11b, a light emitting diode (LED) emitting visible light, as well as light sources emitting near infrared or infrared, may be used. The illumination unit 11b is installed at a position capable of illuminating an authenticated region such as a hand of the user who is in the viewing area that is detected by the sensor unit 11a, for example. When the illumination unit 11b has directivity, the illumination unit 11b may also be provided with a mechanical unit for allowing the direction in which the illuminating light is output to be adjusted depending on the position of the user in the viewing area.

The image sensor 11c is a sensor that converts the light incident from a lens not illustrated into an electric signal. As a possible implementation of the image sensor 11c, a charge coupled device (CCD) or a complementary metal oxide semiconductor (CMOS) may be used. The image sensor 11c is installed at a position allowing the authenticated region such as a hand of the user in the viewing area detected by the sensor unit 11a to be imaged, for example. The image sensor 11c may also be provided with a mechanical unit for adjusting the angular field of the image capturing apparatus 11 depending on the position where the user is present in the viewing area so that the authenticated region of the user can be imaged on the image sensor 11c. An image captured by the image sensor 11c is stored in the image storage unit 11e by the image capturing control unit 11f which will be explained later.

The communicating unit 11d is a processing unit that transmits and receives data to and from other apparatuses including the authentication apparatus 12. As a possible implementation, the communicating unit 11d transmits a notification indicating that a user is detected or an image stored in the image storage unit 11e to the authentication apparatus 12, and receives an image capturing instruction from the authentication apparatus 12. The communicating unit 11d may be connected to a communicating unit 12a included in the authentication apparatus 12 over a wire, such as a connector or a cabled local area network (LAN), or wirelessly, e.g., over the Bluetooth (registered trademark), infrared communication, or a wireless LAN.

The image storage unit 11e is a storage device storing therein images. As an example, the image storage unit 11e stores therein an image captured by the image capturing control unit 11f. As another example, the image storage unit 11e is accessed when an image stored in the image storage unit 11e is read before such an image is transferred to the authentication apparatus 12. An image stored in the image storage unit 11e may be deleted after the image is transmitted to the authentication apparatus 12.

The image capturing control unit 11f is a processing unit that controls the illumination unit 11b and the image sensor 11c to allow an image of a subject to be captured. As a possible implementation, the image capturing control unit 11f notifies the authentication apparatus 12 that a user is detected when the sensor unit 11a detects a user in the viewing area. When the authentication apparatus 12 receives a notification of a user being detected, the image capturing control unit 11f

receives an image capturing instruction from the authentication apparatus 12, as a response to such a notification. The “image capturing instruction” herein includes image capturing parameters related to an “OFF image” captured in an OFF state in which the illumination is turned OFF, and to an “ON image” captured in an ON state in which the illumination is turned ON. An example of the image capturing parameters includes an exposure time E for which the image sensor 11c is exposed to light that is imaged through the lens not illustrated, and a divisor N by which the exposure time E is divided. When such an image capturing instruction is received, the image capturing control unit 11f computes a unit exposure time E' representing an exposure time for a single piece of image, by dividing the exposure time E by the divisor N included in the image capturing instruction. After computing the unit exposure time E', the image capturing control unit 11f captures N pieces of OFF image and N pieces of ON image.

The image capturing control unit 11f captures the OFF images by turning OFF the illumination unit 11b before and after capturing N pieces of ON images. For example, after turning OFF the illumination unit 11b and capturing N/2 pieces of OFF images, the image capturing control unit 11f turns ON the illumination unit 11b and captures N pieces of ON images. The image capturing control unit 11f then turns OFF the illumination unit 11b again, and captures N/2 pieces of OFF images.

FIG. 2 is a schematic of an image capturing sequence. Illustrated as an example in FIG. 2 is an image capturing sequence in an example when the divisor N is “4”. As illustrated in FIG. 2, the image capturing control unit 11f keeps the illumination unit 11b OFF for a period from time T0 to time T2, and closes the shutter temporarily at time T1. The image capturing control unit 11f then causes the image storage unit 11e to store therein an OFF image a1 acquired through the exposure over a period “T0 to T1”, and to store therein an OFF image a2 acquired through the exposure over a period “T1 to T2”. The image capturing control unit 11f then switches the illumination unit 11b from OFF to ON at time T2. Because completely switching the illumination unit 11b from OFF to ON takes a certain length of time, the image capturing control unit 11f performs null write to the image storage unit 11e for an image acquired through the exposure over a period “T2 to T3”, assuming that switching from OFF to ON takes time from time T2 to time T3. Such null write is performed because any image acquired before switching to ON or OFF is completed is not used in the authentication.

The image capturing control unit 11f keeps the illumination unit 11b ON for a period from time T3 to time T6, and closes the shutter temporarily at time T4, time T5, and time T6. As a result, an ON image b1 acquired through the exposure over a period “T3 to T4”, an ON image b2 acquired through the exposure over a period “T4 to T5”, an ON image b3 acquired through the exposure over a period “T5 to T6”, and an ON image b4 acquired through the exposure over a period “T6 to T7” are stored in the order listed herein in the image storage unit 11e. The image capturing control unit 11f then switches the illumination unit 11b from ON to OFF at time T7. The image capturing control unit 11f performs null write to the image storage unit 11e for an image acquired through the exposure over a period “T7 to T8”. The image capturing control unit 11f then keeps the illumination unit 11b OFF for a period from time T8 to time T10, and closes the shutter temporarily at time T9 and time T10. In this manner, the image capturing control unit 11f stores an ON image a4 acquired through the exposure over a period “T9 to T10” in

the image storage unit 11e, after storing an ON image a3 acquired through the exposure over a period “T8 to T9” in the image storage unit 11e.

The OFF images and the ON images stored in the image storage unit 11e are sequentially read by the image capturing control unit 11f, and transmitted to the authentication apparatus 12 via the communicating unit 11d. These OFF images and the ON images may be assigned with identification information such as a frame number in an ascending or descending order of the sequence in which these images are captured, when these images are stored in the image storage unit 11e or when these images are transmitted to the authentication apparatus 12.

By turning OFF the illumination unit 11b and capturing N/2 OFF images before and after N ON images are captured, the time and the number of times for null write can be reduced. FIG. 3 is a schematic of an example of an image capturing sequence. Illustrated in FIG. 3 is a sequence in which four OFF images and four ON images are captured alternately. As illustrated in FIG. 3, when OFF images and ON images are captured alternately, null write is performed for images for a period “T1 to T2”, a period “T3 to T4”, a period “T5 to T6”, and a period “T7 to T8”, as well as for images for a period “T9 to T10”, a period “T11 to T12”, period “T13 to T14”, and a period “T15 to T16”. In other words, when OFF images and ON images are captured alternately, null write is performed eight times in total. When the illumination unit 11b is turned OFF before and after N pieces of ON images are captured and then N/2 pieces of OFF images are captured, null write is made only twice. Because the image capturing apparatus 11 according to the first embodiment can reduce the time and the number of times for null write, idle time for capturing images can be reduced.

As the image capturing control unit 11f, various types of integrated circuits or electronic circuits may be used. An example of an integrated circuit includes an application specific integrated circuit (ASIC). Examples of an electronic circuit include a central processing unit (CPU) and a micro-processing unit (MPU).

As the image storage unit 11e, a semiconductor memory device or a storage device may be used. Examples of the semiconductor memory device include a video random access memory (VRAM), a random access memory (RAM), and a flash memory. Examples of the storage device include storage devices such as a hard disk or an optical disk.

Configuration of Authentication Apparatus 12

A functional configuration of the authentication apparatus 12 according to the first embodiment will now be explained. As illustrated in FIG. 1, the authentication apparatus 12 includes the communicating unit 12a, a storage unit 12b, an image capturing instructing unit 12c, a determining unit 12d, a computing unit 12e, an integrating unit 12f, and an authenticating unit 12g.

Among these units, the communicating unit 12a is a processing unit that transmits and receives data to and from other apparatuses including the image capturing apparatus 11. As a possible implementation, the communicating unit 12a receives a notification indicating that a user is detected, OFF images, and ON images from the image capturing apparatus 11, and transmits an image capturing instruction. The communicating unit 12a may be connected to the communicating unit 11d in the image capturing apparatus 11 over a wire, such as a connector or a cabled LAN, or wirelessly, e.g., over the Bluetooth (registered trademark), infrared communication, or a wireless LAN.

The storage unit 12b is a storage device storing therein various types of information. As a possible implementation,

the storage unit **12b** stores therein OFF images, ON images, a difference image representing a difference between an OFF image and an ON image, an integrated image in which difference images are integrated, and a gesture pattern image that is matched against the integrated image. As an example, when OFF images or ON images are received from the image capturing apparatus **11**, the storage unit **12b** stores therein the OFF images or the ON images. As another example, when a difference between an OFF image and an ON image is computed, the storage unit **12b** stores therein the difference image. As still another example, the storage unit **12b** stores therein an integrated image in which a plurality of difference images are integrated. As another example, when a gesture authentication is to be executed, the storage unit **12b** is accessed by the authenticating unit **12g**, which will be described later, so as to allow a reference to an integrated image and a gesture pattern image against which the integrated image is matched.

The image capturing instructing unit **12c** is a processing unit that gives an image capturing instruction to the image capturing apparatus **11**. As a possible implementation, when a notification indicating that a user is in the viewing area is received from the sensor unit **11a** in the image capturing apparatus **11**, the image capturing instructing unit **12c** causes the determining unit **12d**, which will be described later, to determine a divisor N , which is to be included in the image capturing parameters. The image capturing instructing unit **12c** then transmits an image capturing instruction containing the image capturing parameters including the divisor N determined by the determining unit **12d** and the exposure time E to the image capturing apparatus **11**. The image capturing instructing unit **12c** then stores OFF images and ON images received from the image capturing apparatus **11** in the storage unit **12b**. When N pieces of OFF images and N pieces of ON images are stored in the storage unit **12b**, the image capturing instructing unit **12c** gives an instruction for computing a difference image to the computing unit **12e**, which will be described later.

The determining unit **12d** is a processing unit that determines the divisor N based on the intensity of external light. As a possible implementation, the determining unit **12d** sets an initial value N_0 that is preferably applied in an environment without any external light to the divisor N , and sets the unit exposure time E' to E/N that is computed from the exposure time E and the divisor N , before causing the image capturing apparatus **11** to capture a predetermined number of ON images. Because the ON images thus captured by the image capturing apparatus **11** are used for establishing the divisor N , the number of ON images thus captured does not necessarily need to be in plurality, as long as at least one ON image is captured. Furthermore, because it is intended herein to explore the optimal divisor by setting the initial divisor small and gradually increasing the divisor, it is assumed herein that "1" is set to the initial value N_0 , as an example. However, it is also possible to explore the optimal divisor by initially setting a divisor expected to be the largest, and by gradually reducing the divisor.

After causing the image capturing apparatus **11** to capture the ON images, the determining unit **12d** computes an external light evaluation value Ex , serving as an index for the intensity of external light, from the ON images. As examples of the method for computing the external light evaluation value Ex , various calculations may be used depending on characteristics or the like used in the authentication. For example, a small area C may be set at the center of the ON image, and a ratio of pixels with saturation with respect to the small area C may be computed as the external light evaluation

value Ex . The optimal size or the position of the small area C varies depending on the subject assumed or how the subject is illuminated. For example, the small area C is established correspondingly to an environment in which the images are captured, e.g., considering whether such images are captured in a condition resulting in the highest luminance at the center of the image or in a condition resulting in a high luminance in a specific area of the image. Furthermore, an average luminance, a maximum luminance, a minimum luminance, a median luminance, or a most frequent luminance may be used as an index, instead of the saturation pixel ratio serving as the index.

The determining unit **12d** then determines if the external light evaluation value Lx is lower than a predetermined threshold Th . If the external light evaluation value is lower than the predetermined threshold, it can be assumed that saturation is not likely to be produced on images when the images are captured based on the unit exposure time E' . In such a case, the determining unit **12d** determines the divisor N used previously as the divisor N . If the external light evaluation value Ex is equal to or higher than the predetermined threshold Th , it can be assumed that saturation is likely to be produced on ON images when the images are captured with the unit exposure time E' . In such a case, the determining unit **12d** updates the divisor N to a value larger than the previous value, e.g., a value twice the previous divisor. The determining unit **12d** repeats the process of updating the divisor, setting a unit exposure time E' , and computing the external light evaluation value Ex , until the external light evaluation value Ex reaches a value lower than the threshold Th . The divisor N thus determined is output to the image capturing instructing unit **12c**.

The computing unit **12e** is a processing unit that computes a difference image using an OFF image and an ON image stored in the storage unit **12b**. As a possible implementation, when an instruction for computing a difference image is received from the image capturing instructing unit **12c**, the computing unit **12e** reads N pieces of OFF images and N pieces of ON images stored in the storage unit **12b**. The computing unit **12e** then determines N pairs of an OFF image and an ON image from the OFF images and the N pieces of ON images read from the storage unit **12b**. It is preferable for such images to be paired into N pairs in a manner so that the sum of differences between the time at which the OFF images are captured and the time at which the respective ON images are captured becomes the smallest. For example, the computing unit **12e** pairs an OFF image and an ON image each of which is captured at the earliest timing, among the N pieces of OFF images and the N pieces of ON images. The computing unit **12e** then computes the difference between the pixel values in the OFF image and the respective pixel values in the ON image in each of these pairs. In this manner, the computing unit **12e** computes N pieces of difference images. The computing unit **12e** then stores the N pieces of difference images in the storage unit **12b**.

To explain using the example illustrated in FIG. 2, the computing unit **12e** establishes four pairs by pairing the OFF image **a2** and the ON image **b2**, pairing the OFF image **a2** and the ON image **b2**, pairing the OFF image **a3** and the ON image **b3**, and pairing the OFF image **a4** and the ON image **b4**. The computing unit **12e** then computes a difference image **ab1** by computing pixel value differences between the pixels in the OFF image **a1** and those in the ON image **b1**. In the same manner, the computing unit **12e** computes a difference image **ab2** from the OFF image **a2** and the ON image **b2**, computes a difference image **ab3** from the OFF image **a3** and the ON image **b3**, and computes a difference image **ab4** from the OFF

image a4 and the ON image b4. By computing the difference images ab1 to ab4 in the manner described above, the difference in time between when the ON image is captured and when the OFF image is captured can be kept to two unit exposure times E' at a maximum.

When used is the image capturing sequence in which the illumination unit 11b is turned OFF and N/2 pieces of OFF images are captured before and after N pieces of ON images are captured, the influence of time-dependent variations in the position of the subject or the intensity of external light can be reduced, compared with when another image capturing sequence is used.

FIGS. 4 and 5 are schematics of examples of an image capturing sequence. FIG. 6 is a schematic of an example of a relation between time and a variation level. Illustrated in FIG. 4 is an image capturing sequence in which an ON image is captured continuously for four times, and then OFF image is captured continuously for four times. Illustrated in FIG. 5 is an image capturing sequence that is the same as that illustrated in FIG. 2. FIG. 6 schematically illustrates a degree by which the position of the subject or the intensity of external light changes from time t1 to time t8, each at which an image is captured, and reference time t positioned at the center of the time while which these eight images are captured.

Because ON images $\beta 1$ to $\beta 4$ illustrated in FIG. 4 are captured at "t1", "t2", "t3", and "t4", respectively, the degree of change from the reference time t becomes "+4", "+3", "+2", and "+1", as illustrated in FIG. 6. Therefore, the total degree of change for the ON images $\beta 1$ to $\beta 4$ reaches "10". Because OFF images $\alpha 1$ to $\alpha 4$ are captured at "t5", "t6", "t7", and "t8", respectively, the degree of change from the reference time becomes "-4", "-3", "-2", and "-1", respectively, as illustrated in FIG. 6. Therefore, the total degree of change for the OFF images $\alpha 1$ to $\alpha 4$ also reaches "10". Therefore, when difference images $\alpha \beta 1$ to $\alpha \beta 4$ are computed, the degree of change results in "20".

By contrast, because the OFF images a1 to a4 illustrated in FIG. 5 are captured at "t1", "t2", "t7", and "t8", respectively, the degree of change from the reference time t becomes "+4", "+3", "-3", and "-4", as illustrated in FIG. 6. Therefore, the total degree of change for the OFF images a1 to a4 can be suppressed to "0". Because the ON images b1 to b4 are captured at "t3", "t4", "t5", and "t6", respectively, the degree of change from the reference time t becomes "+2", "+1", "-2", and "-1", respectively, as illustrated in FIG. 6. Therefore, the total degree of change for the ON images b1 to b4 can also be suppressed to "0". Therefore, when difference images $\alpha \beta 1$ to $\alpha \beta 4$ are computed, the degree of change can be suppressed to "0".

In particular, when used is an image capturing sequence in which the illumination ON images are positioned at the center, the illumination ON images can be captured continuously. Because the illumination ON images include external light as well as the light from the illumination itself, such images have higher luminance than that in the illumination OFF images. Therefore, illumination ON images are more affected by variations in the subject or the external light than the illumination OFF images. By capturing such illumination ON images continuously, the influence of such variations can be further reduced.

Based on the reason described above, it can be understood that, when the image capturing sequence illustrated in FIG. 5 is used, the influence of time-dependent variations in the position of the subject or the intensity of external light can be reduced, compared with when the image capturing sequence illustrated in FIG. 4 is used.

The integrating unit 12f is a processing unit that integrates difference images. As a possible implementation, when N pieces of difference images are computed by the computing unit 12e, the integrating unit 12f reads the N pieces of difference images from the storage unit 12b, and acquires the sum of the pixel values for each pixel of the N pieces of difference images read from the storage unit 12b. In this manner, a single piece of integrated image can be generated from the N pieces of difference images. Because the difference between each of the ON images and each of the OFF images has been computed, the integrated image thus generated will be an image in which the influence of external light is suppressed, represented as if the images were captured only with the illumination from the illumination unit 11b. Furthermore, because difference images captured based on a divided exposure time are integrated, images can be captured while keeping the exposure time short. As a result, saturation is suppressed in the resultant integrated image, even when strong external light is present. Therefore, it is possible to acquire an image in which the authenticated region of the user who is in the viewing area of the television receiver is captured appropriately.

The authenticating unit 12g is a processing unit that authenticates a gesture of a subject using an integrated image generated by the integrating unit 12f. As a possible implementation, the authenticating unit 12g extracts an image portion that is similar to the shape of a hand from the integrated image as an image to be authenticated, by applying image processing such as edge detection or skin color detection to the integrated image. The authenticating unit 12g then executes an image matching process such as pattern matching between the image to be authenticated extracted via the image processing and the gesture pattern image stored in the storage unit 12b. An example of the gesture pattern image includes an image representing a pattern of the shape of a hand rising fingers in the number corresponding to a channel number. For example, the authenticating unit 12g computes the similarity between each of the gesture pattern images and the image to be authenticated. The authenticating unit 12g then determines if there is any gesture pattern image with a similarity to the authenticated image higher than a predetermined threshold. If there is any pattern image with a similarity higher than the threshold, the authenticating unit 12g outputs a gesture corresponding to the pattern image or a command corresponding to the gesture to the television receiver. In this manner, the television receiver is caused to execute a command corresponding to the gesture, that is, to change the channel, in the example mentioned above.

As the image capturing instructing unit 12c, the determining unit 12d, the computing unit 12e, the integrating unit 12f, and the authenticating unit 12g, various types of integrated circuits or electronic circuits may be used. An example of an integrated circuit includes an ASIC. Examples of an electronic circuit include a CPU or an MPU.

As the storage unit 12b, a semiconductor memory device or a storage device may be used. Examples of the semiconductor memory device include a VRAM, a PAM, and a flash memory. Examples of the storage device include storage devices such as a hard disk or an optical disk.

Sequence of Processes

The sequence of processes performed by the gesture authentication system 10 according to the first embodiment will now be explained. In this section, (1) an authenticating process performed by the gesture authentication system 10 will be explained to begin with, and (2) a divisor determining process and (3) an image capturing process included in the authenticating process will then be explained in detail.

11

(1) Authenticating Process

FIG. 7 is a flowchart illustrating an authenticating process according to the first embodiment. This authenticating process is initiated when the sensor unit 11a detects a user in the viewing area of the television receiver. As illustrated in FIG. 7, when the sensor unit 11a detects a user in the viewing area (Step S101), the image capturing control unit 11f notifies the authentication apparatus 12 that a user is detected in the viewing area (Step S102).

In response, the determining unit 12d in the authentication apparatus 12 executes a "divisor determining process" for determining the divisor N by which the exposure time E is divided (Step S103). The image capturing instructing unit 12c then sends an image capturing instruction containing image capturing parameters including the divisor N determined by the determining unit 12d to the authentication apparatus 12 (Step S104).

The image capturing control unit 11f receiving the image capturing instruction then executes an "image capturing process" in which N pieces of OFF images and N pieces of ON images are captured, in the order of N/2 pieces of OFF images, N pieces of ON images, and N/2 pieces of OFF images (Step S105). The image capturing control unit 11f then transfers the N pieces of OFF images and the N pieces of ON images to the authentication apparatus 12 via the communicating unit 11d (Step S106).

The image capturing instructing unit 12c in the authentication apparatus 12 then stores the N pieces of OFF images and the N pieces of ON images in the storage unit 12b (Step S107). The computing unit 12e then determines N pairs of an OFF image and an ON image, and computes N pieces of difference images from the respective pairs of an OFF image and an ON image (Step S108). The computing unit 12e then stores the N pieces of difference images computed at Step S108 in the storage unit 12b (Step S109).

The integrating unit 12f then generates a single piece of integrated image from the N pieces of difference images, by acquiring the sum of the pixel values across the N pieces of difference images stored in the storage unit 12b (Step S110). The integrating unit 12f then stores the integrated image generated at Step S110 in the storage unit 12b (Step S111).

The authenticating unit 12g then computes a similarity between an image of the authenticated region detected from the integrated image stored in the storage unit 12b at Step S111 and each of the gesture pattern images stored in the storage unit 12b (Step S112).

If any pattern image has a similarity higher than the predetermined threshold (Yes at Step S113), the authenticating unit 12g executes the following process. In other words, the authenticating unit 12g outputs a gesture corresponding to the pattern image or a command corresponding to the gesture to the television receiver (Step S114), and the process is ended. If no pattern image has a similarity higher than the predetermined threshold (No at Step S113), the process is ended at this point.

(2) Divisor Determining Process

FIG. 8 is a flowchart illustrating a divisor determining process according to the first embodiment. This process is initiated when the process at Step S102 is executed in the authenticating process illustrated in FIG. 7, that is, when a notification of a user detection is received from the image capturing apparatus 11.

As illustrated in FIG. 8, the determining unit 12d sets the initial value N_0 preferably applied in an environment without any external light to the divisor N (Step S201). The determining unit 12d then sets the unit exposure time E' to E/N computed from the exposure time E and the divisor N (Step S202).

12

The determining unit 12d then causes the image capturing apparatus 11 to capture a predetermined number of ON images based on the unit exposure time E' (Step S203). The determining unit 12d then computes an external light evaluation value E_x serving as an index for the intensity of external light from the ON images captured at Step S203 (Step S204). The determining unit 12d then determines if the external light evaluation value E_x is lower than a predetermined threshold Th (Step S205).

If the external light evaluation value E_x is equal to or higher than the predetermined threshold Th (No at Step S205), it can be assumed that saturation is likely to be produced on images when the images are captured based on the unit exposure time E' . In such a case, the determining unit 12d updates the divisor N to a value larger than the previous value, e.g., a value twice the previous divisor (Step S206). The system control then goes to Step S202, and the determining unit 12d repeats the process of updating the divisor, setting a unit exposure time E' , causing the image capturing apparatus 11 to capture ON images, and computing the external light evaluation value E_x , until the external light evaluation value E_x reaches a value lower than the threshold Th .

If the external light evaluation value is lower than the predetermined threshold (Yes at Step S205), it can be assumed that saturation is not likely to be produced on ON images when the images are captured based on the unit exposure time E' . In such a case, the determining unit 12d outputs the divisor N used at Step S201 or Step S206 to the image capturing instructing unit 12c (Step S207), and the process is ended.

(3) Image Capturing Process

FIG. 9 is a flowchart illustrating an image capturing process according to the first embodiment. The image capturing process is initiated when the process at Step S104 is executed in the authenticating process illustrated in FIG. 7, that is, when an image capturing instruction is received from the authentication apparatus 12.

As illustrated in FIG. 9, if an image capturing instruction containing the exposure time E, the divisor N, and the like is received from the authentication apparatus 12, the image capturing control unit 11f computes the unit exposure time E' representing an exposure time for a single piece of image, by dividing the exposure time E by the divisor N (Step S301).

The image capturing control unit 11f then turns OFF the illumination unit 11b, and captures N/2 pieces of OFF images (Step S302). The image capturing control unit 11f then turns ON the illumination unit 11b, and captures N pieces of ON images (Step S303). The image capturing control unit 11f then turns OFF the illumination unit 11b, and captures N/2 pieces of OFF images (Step S304).

Finally, the image capturing control unit 11f stores the N pieces of OFF images and the N pieces of ON images captured at Steps S302 to S304 in the image storage unit 11e (Step S305), and the process is ended.

Advantageous Effects Achieved by First Embodiment

As described above, the gesture authentication system 10 according to the first embodiment turns OFF the illumination unit 11b and captures OFF images before and after N pieces of ON images are captured. Therefore, in the gesture authentication system 10 according to the first embodiment, because the frequency at which the illumination is switched from ON to OFF and switched from OFF to ON can be reduced, the frequency of and the time for null write can be reduced. As a result, idle time for capturing images can be reduced. Therefore, the gesture authentication system 10 according to the first embodiment can reduce the image capturing time.

13

Furthermore, in the gesture authentication system 10 according to the first embodiment, the authentication apparatus 12 executes the process of capturing ON images and determining the divisor through trial-and-error, the process of computing the difference between an OFF image and an ON image, the process of integrating the difference images, and the like. Therefore, the gesture authentication system 10 according to the first embodiment can simplify the functional configuration of the image capturing apparatus 11. There are more advantageous effects that can be achieved by simplifying the image capturing apparatus 11. For example, in a possible configuration in which a gesture authentication is executed, the authentication apparatus 12 may be built into a fixed place, e.g., near the television receiver or in the television receiver, but the place where the image capturing apparatus 11 is installed may be changed depending on how the image capturing apparatus 11 is used by the user. Furthermore, another possible configuration of the system may include one authentication apparatus 12 and a plurality of image capturing apparatuses 11. When such a system configuration is used, the entire cost can be reduced when the configuration of the image capturing apparatus 11 is simplified.

Furthermore, in the gesture authentication system 10 according to the first embodiment, OFF images that are divided into equal groups are captured before and after the ON images are captured, an ON image and an OFF image at the same order are in the order of the time at which these images are captured, and difference images are computed for each of these pairs. Therefore, for example, the influence of variations such as positional changes, e.g., those of when the hand of the subject gradually moves down, changes in the external light intensity due to a blocking object, and the like can be evenly allocated to the OFF image and the ON image for which a difference is computed. Therefore, difference images that are less affected by such variations can be computed stably.

Furthermore, because the ON images are captured continuously at the center of the image capturing sequence, the influence of the variations in the external light and the subject can be reduced. This is because an ON image has higher luminance, an ON image is more influenced by such variations than an OFF image. Therefore, by capturing the ON images continuously at the center of the image capturing sequence, the influence of such variations can be further reduced.

Furthermore, in the gesture authentication system 10 according to the first embodiment, because an OFF image and an ON image are captured an even number of times, redundant OFF images and ON images not used in computing a difference image are not captured. Therefore, the image capturing time can be reduced.

Furthermore, in the gesture authentication system 10 according to the first embodiment, because the image capturing time is reduced, extension of time in which the images are captured can be suppressed even when used is an image sensor capturing images at a low rate and a long interval. Because an inexpensive image sensor can be used, costs can be reduced.

[b] Second Embodiment

Explained in the first embodiment is an example in which the authentication apparatus 12 is caused to generate difference images and an integrated image. However, it is not necessarily need to be the authentication apparatus 12 that generates difference images and an integrated image. Furthermore, explained in the first embodiment is an example in which the image capturing apparatus 11 is caused to capture

14

the images to be used in the gesture authentication, but the image capturing apparatus 11 may also capture images to be used in another type of authentication or determination. Therefore, explained in a second embodiment of the present invention is an example in which an image capturing apparatus 21 is caused to capture OFF images and ON images of the face of a person who is a subject, to generate difference images and an integrated image, and an authentication apparatus 22 is caused to execute a face authentication using the integrated image.

Configuration of Face Authentication System

FIG. 10 is a block diagram illustrating functional configurations of apparatuses included in a face authentication system according to the second embodiment. This face authentication system 20 illustrated in FIG. 10 performs a face authentication by matching an integrated image generated from OFF images and ON images in which the face of a person is captured against a registered image that is a pre-registered integrated image of the face of a person based upon which authentication is determined to be successful when the system performs the authentication. In the following description of the second embodiment, it is assumed that the face authentication is used in controlling an entry and exit of someone into and from a gate installed in a facility or at the boundary of a room or a booth of a facility.

As illustrated in FIG. 10, the face authentication system 20 includes the image capturing apparatus 21 and the authentication apparatus 22. Among these apparatuses, the image capturing apparatus 21 is installed at a position allowing the face of a person passing through a gate to be captured in the angle of view of the image capturing apparatus 21, as an example, so that an image of the face of a person passing through the gate can be captured. As an example, the authentication apparatus 22 may be implemented as a server connected to a plurality of the image capturing apparatuses 21. Alternatively, a function for performing the face authentication may be incorporated into the image capturing apparatus 21 so that face authentication can be performed on standalone basis.

Configuration of Image Capturing Apparatus 21

To begin with, a functional configuration of the image capturing apparatus 21 according to the second embodiment will be explained. Comparing with the image capturing apparatus 11 illustrated in FIG. 1, the image capturing apparatus 21 illustrated in FIG. 10 includes the following functional units, instead of the sensor unit 11a, the illumination unit 11b, the image sensor 11c, the communicating unit 11d, the image storage unit 11e, and the image capturing control unit 11f. In other words, the image capturing apparatus 21 includes a sensor unit 21a, an illumination unit 21b, an image sensor 21c, a communicating unit 21d, an image storage unit 21e, and an image capturing control unit 21f.

Because the sensor unit 21a, the illumination unit 21b, the image sensor 21c, the communicating unit 21d, the image storage unit 21e, the image capturing control unit 21f, a determining unit 21g, a computing unit 21h, and an integrating unit 21j have basic functions that are the same as those of the respective functional units illustrated in FIG. 1, only the differences are explained hereunder.

Among these units, the sensor unit 21a is different from the sensor unit 11a illustrated in FIG. 1 in that the sensor unit 21a detects a user approaching the gate. Therefore, the sensor unit 21a monitors an area where people pass through the gate, e.g., a radius of 1 meter from the gate, as an example. When the sensor unit 21a detects a user passing through such a pass-through area, the sensor unit 21a notifies the image capturing

15

control unit **21f**, which will be described later, of entry of the user into the gate pass-through area.

The illumination unit **21b** is different from the illumination unit **11b** illustrated in FIG. 1 in that the illumination unit **21b** illuminates the face of a user approaching the gate. Therefore, the illumination unit **21b** is installed at a position capable of illuminating the authenticated region of the user, e.g., the face of the user, who is in the pass-through area of the gate detected by the sensor unit **21a**. When the illumination unit **21b** has directivity, the illumination unit **21b** may also be provided with a mechanical unit for allowing the direction in which the illuminating light is output to be adjusted depending on the position of the user in the pass-through area of the gate.

The image sensor **21c** is different from the image sensor **11c** illustrated in FIG. 1 in that the image sensor **21c** is installed at a position enabling the face of the user who is in the pass-through area of the gate to be imaged on a lens not illustrated. The image sensor **21c** may be provided with a mechanical unit for adjusting the angular field of the image capturing apparatus **21** depending on the position where the user is present in the pass-through area of the gate so as to allow the authenticated region of the user to be imaged on the image sensor **21c**. The image capturing control unit **21f**, which will be described later, stores the image captured by the image sensor **21c** in the image storage unit **21e**.

The communicating unit **21d** is different from the communicating unit **11d** illustrated in FIG. 1 in that the communicating unit **21d** transmits and receives different types of data to and from other apparatuses including the authentication apparatus **22**. For example, the communicating unit **21d** transmits a notification of a user entering the pass-through area of the gate or an integrated image to the authentication apparatus **22**. The communicating unit **21d** also receives an image capturing ending instruction for ending capturing images of the face of the user who have entered the pass-through area of the gate, or a registered image generating instruction for generating a registered image.

The image storage unit **21e** is different from the image storage unit **11e** illustrated in FIG. 1 in that the image storage unit **21e** stores therein different types of data. As mentioned earlier, in the second embodiment, the image capturing apparatus **21** starts capturing OFF images and ON images, and executes calculations of the difference images and generation of the integrated image. Therefore, in the image storage unit **21e** stores therein difference images and an integrated image, in addition to the original images such as OFF images and ON images received from the image sensor **21c**.

The image capturing control unit **21f** is different from the image capturing control unit **11f** illustrated in FIG. 1 in that the image capturing process is triggered differently. In other words, because the authentication apparatus **22** illustrated in FIG. 10 performs a face authentication, not the gesture authentication executed in the authentication apparatus **12** illustrated in FIG. 1, the image capturing control unit **21f** executes the image capturing process, which is executed by the image capturing control unit **11f** illustrated in FIG. 1, twice, once at a stage registering the face of a person permitted to go through the gate, and another time at a stage generating the face of a user entering gate.

Furthermore, the image capturing apparatus **21** illustrated in FIG. 10 further includes the determining unit **21g**, the computing unit **21h**, and the integrating unit **21j**, as functional units not illustrated in FIG. 1. The determining unit **21g**, the computing unit **21h**, and the integrating unit **21j** are different from the determining unit **12d**, the computing unit **12e**, and the integrating unit **12f** included in the authentication apparatus **12** illustrated in FIG. 1 in that these functional units are

16

provided to the apparatus capturing images. In addition, the determining unit **21g**, the computing unit **21h**, and the integrating unit **21j** are different in performing the process at two stages, in the same manner as the process performed by the image capturing control unit **21f**.

Configuration of Authentication Apparatus **22**

A functional configuration of the authentication apparatus **22** according to the second embodiment will now be explained. The authentication apparatus **22** illustrated in FIG. 10 includes a communicating unit **22a** and a storage unit **22b**, instead of the communicating unit **12a** and the storage unit **12b** provided to the authentication apparatus **12** illustrated in FIG. 1.

Because the communicating unit **22a** and the storage unit **22b** have basic functions that are the same as those of the corresponding functional units illustrated in FIG. 1, only the differences are explained hereunder.

The communicating unit **22a** is different from the communicating unit **12a** illustrated in FIG. 1 in that the communicating unit **22a** transmits and receives different types of data to and from other apparatuses including the image capturing apparatus **21**. For example, the communicating unit **22a** transmits an image capturing ending instruction and a registered image generating instruction to the image capturing apparatus **21**. The communicating unit **22a** also receives an integrated image and a notification of a user entering the pass-through area of the gate from the image capturing apparatus **21**.

The storage unit **22b** is different from the storage unit **12b** illustrated in FIG. 1 in that the storage unit **22b** stores therein different types of data. In other words, because, in the second embodiment, the image capturing apparatus **21** not only captures OFF images and ON images, but also performs computation of difference images and generation of an integrated image, only the integrated image is stored in the storage unit **22b**, without storing therein OFF images, ON images, and difference images. For example, when the sensor unit **21a** detects a user entering the pass-through area of the gate, the storage unit **22b** stores therein a registered image against which the integrated image of the user generated by the image capturing apparatus **21** is compared. Explained herein is an example in which stored as a registered image is an integrated image of a permitted person who is permitted to make an entry or exit through the gate by the administrator of the face authentication system **20**, as well as characterizing quantities extracted from the integrated image. However, alternatively, only one of the integrated image or the characterizing quantities of the permitted person may also be stored.

Furthermore, the authentication apparatus **22** illustrated in FIG. 10 includes a receiving unit **22g**, an authenticating unit **22h**, and a retry control unit **22j**, as functional units not illustrated in FIG. 1.

The receiving unit **22g** is a processing unit that receives an instruction for generating a registered image. As a possible implementation of the receiving unit **22g**, various types of user interface such as a keyboard or a touch panel can be used. For example, the receiving unit **22g** receives an instruction for generating a registered image of a permitted person who is permitted to make an entry or exit through the gate from the administrator of the face authentication system **20**, and notifies the image capturing apparatus **21** of the instruction for generating the registered image. In this manner, the image capturing apparatus **21** is caused to capture the OFF images and the ON images of the face of a person whose registered image is to be generated, to compute difference images, and

17

to generate an integrated image. The receiving unit **22g** may also be independently implemented outside of the authentication apparatus **22**.

The authenticating unit **22h** is a processing unit that performs a face authentication of a subject using an integrated image of a user received from the image capturing apparatus **21** and a registered image of a permitted person stored in the storage unit **22b**. As a possible implementation, the authenticating unit **22h** detects an image of a portion corresponding to the face by executing template matching to an integrated image. The authenticating unit **22h** extracts geometric characteristics such as the shape or the size of a part of the face, such as eyes, a nose, a mouth, and ears, from the image corresponding to the face portion detected by the template matching as characterizing quantities. The authenticating unit **22h** then computes a similarity *S* between each of the registered images stored in the storage unit **22b** and characterizing quantities. The authenticating unit **22h** determines that the authentication is successful if there is any registered image resulting in a similarity *S* higher than the predetermined threshold. In such a case, it is not necessary to retry the authentication. Therefore, the authenticating unit **22h** notifies the image capturing apparatus **21** of an image capturing ending instruction, and outputs a notification of the successful authentication to a device unlocking the door, for example. As a result, the user having entered the pass-through area of the gate is permitted to enter or exit. By contrast, if there is only some registered image resulting in a similarity *S* less than the predetermined threshold, the authenticating unit **22h** determines that the authentication has failed. In such a case, the retry control unit **22j**, which will be described later, is caused to determine if the authentication has been retried for a certain number of times. The threshold compared with the similarity *S* can be specified in any way. For example, the threshold can be lowered when it is preferable to reduce the false rejection rate, and can be raised when it is preferable to reduce the false acceptance rate.

The retry control unit **22j** is a processing unit that controls retries of the face authentication. As a possible implementation, the retry control unit **22j** initializes a retry count *R* recorded in an internal memory not illustrated to zero when a user entering the pass-through area of the gate is detected. The retry control unit **22j** then increments the retry count *R* when the authenticating unit **22h** determines that the authentication has failed, and determines if the retry count *R* is equal to or higher than the predetermined threshold. If the retry count *R* is lower than the predetermined threshold, the retry control unit **22j** permits an authentication retry. When an authentication retry is permitted in the manner described above, the retry control unit **22j** causes the authenticating unit **22h** to perform a series of the processes including extracting characterizing quantities from an integrated image of the user, computing a similarity with the registered images, and determining if there is any registered image resulting in a similarity equal to or higher than the threshold. If the retry count is equal to or higher than the threshold, the retry control unit **22j** does not permit any further retry. In such a case, because it is no longer necessary to generate an integrated image of the user, the retry control unit **22j** notifies the image capturing apparatus **21** of an image capturing ending instruction, and outputs a notification of the authentication failure to the image capturing apparatus **21**. The threshold compared with the retry count *B* can be specified in any way. For example, the threshold can be raised when it is preferable to reduce the false rejection rate, and can be lowered when it is preferable to reduce the false acceptance rate.

18

Sequence of Processes

Processes performed by the face authentication system **20** according to the second embodiment will now be explained. Explained hereunder are (1) a registration process for generating and storing a registered image and (2) an authenticating process performed by the face authentication system **20**. The divisor determining process and the image capturing process included in the registration process and the authenticating process are the same as those according to the first embodiment. Therefore, explanations thereof are omitted herein.

(1) Registration Process

FIG. **11** is a flowchart illustrating a registration process according to the second embodiment. This registration process is initiated when the authentication apparatus **22** receives an instruction for generating a registered image from the administrator.

As illustrated in FIG. **11**, when an instruction for generating a registered image is received (Step **S401**), the receiving unit **22g** notifies the image capturing apparatus **21** of the instruction for generating a registered image (Step **S402**).

In response, the determining unit **21g** in the image capturing apparatus **21** executes the “divisor determining process” for determining the divisor *N* by which the exposure time *E* is divided (Step **S403**). At Step **S403**, the determining unit **21g** can execute the same process as that explained in the first embodiment (see FIG. **8**).

The image capturing control unit **21f** then executes the following process using the image capturing parameters including the divisor *N* determined by the determining unit **21g**. In other words, the image capturing control unit **21f** executes the “image capturing process” in which *N* pieces of OFF images and *N* pieces of ON images are captured in the order of *N*/2 pieces of OFF images, *N* pieces of ON images, and *N*/2 pieces of OFF images (Step **S404**). At Step **S404**, the image capturing control unit **21f** can execute the same process as that explained in the first embodiment (see FIG. **9**).

The computing unit **21h** then determines *N* pairs of an OFF image and an ON image, and computes *N* pieces of difference images from the respective pairs of an OFF image and an ON image (Step **S405**). The computing unit **21h** then stores the *N* pieces of difference images computed at Step **S405** in the image storage unit **21e** (Step **S406**).

The integrating unit **21j** then generates a single piece of integrated image from the *N* pieces of difference images, by acquiring the sum of the pixel values across the *N* pieces of difference images stored in the image storage unit **21e** (Step **S407**). The integrating unit **21j** then stores the integrated image generated at Step **S407** in the image storage unit **21e** (Step **S408**). The image capturing apparatus **21** then transfers the integrated image to the authentication apparatus **22** via the communicating unit **21d** (Step **S409**).

The authenticating unit **22h** then stores the integrated image in the storage unit **22b** as a registered image (Step **S410**). The authenticating unit **22h** extracts geometric characteristics such as the shape or the size of a part of the face, e.g., eyes, a nose, a mouth, and ears, from the registered images stored in the storage unit **22b** at Step **S410** as characterizing quantities (Step **S411**). The authenticating unit **22h** then stores the characterizing quantities extracted at Step **S411** in the storage unit **22b**, in a manner associated with the registered image stored at Step **S410** (Step **S412**), and the process is ended.

(2) Authenticating Process

FIG. **12** is a flowchart illustrating an authenticating process according to the second embodiment. This authenticating process is initiated when the sensor unit **21a** detects a user entering the pass-through area of the gate.

19

As illustrated in FIG. 12, when the sensor unit 21a detects a user entering the pass-through area of the gate (Step S601), the image capturing control unit 21f notifies the authentication apparatus 22 of the user entering the pass-through area of the gate (Step S602). The retry control unit 22j receiving the notification at Step S602 initializes the retry count R by setting the retry count R to zero (Step S603).

The determining unit 21g in the authentication apparatus 22 then executes the “divisor determining process” for determining the divisor N by which the exposure time E is divided (Step S604). At Step S604, the determining unit 21g can execute the same process as that explained in the first embodiment (see FIG. 8).

The image capturing control unit 21f then executes the following process using the image capturing parameters including the divisor N determined by the determining unit 21g. In other words, the image capturing control unit 21f executes the “image capturing process” in which N pieces of OFF images and N pieces of ON images are captured in the order of N/2 pieces of OFF images, N pieces of ON images, and N/2 pieces of OFF images (Step S605). At Step S605, the image capturing control unit 21f can execute the same process as that explained in the first embodiment (see FIG. 9).

The computing unit 21h then determines N pairs of an OFF image and an ON image, and computes N pieces of difference images from the respective pairs of an OFF image and an ON image (Step S606). The computing unit 21h then stores the N pieces of difference images computed at Step S606 in the image storage unit 21e (Step S607).

The integrating unit 21j generates a single piece of integrated image from N pieces of difference images, by acquiring the sum of the pixel values across the N pieces of difference images stored in the image storage unit 21e (Step S608). The integrating unit 21j then stores the integrated image generated at Step S608 in the image storage unit 21e (Step S609). The image capturing apparatus 21 then transfers the integrated image to the authentication apparatus 22 via the communicating unit 21d (Step S610).

The process from Step S604 to Step S610 is repeated until an image capturing ending instruction is received from the authentication apparatus 22 (No at Step S611). When an image capturing ending instruction is received (Yes at Step S611), the image capturing apparatus 21 ends the process.

At the same time, the authentication apparatus 22 stores the integrated image received at Step S610 in the storage unit 22b (Step S612). The authenticating unit 22h then extracts characterizing quantities from the integrated image stored in the storage unit 22b at Step S612 (Step S613).

The authenticating unit 22h then computes a similarity S between the characterizing quantities extracted from the integrated image of the user at Step S613 and the characterizing quantities of each of the registered images stored in the storage unit 22b (Step S614).

The authenticating unit 22h then determines if there is any registered image resulting in a similarity S higher than the predetermined threshold (Step S615). If there is no registered image resulting in a similarity S equal to or higher than the threshold (No at Step S615), the retry control unit 22j increments the retry count R (Step S616), and determines if the retry count R is equal to or higher than the predetermined threshold (Step S617). The authentication apparatus 22 repeats the process from Step S612 to Step S616 until the retry count R reaches a value equal to or higher than the predetermined threshold (No at Step S617).

If there is a registered image resulting in a similarity S equal to or higher than the threshold (Yes at Step S615), or if the retry count R reaches a value equal to or higher than the

20

threshold (Yes at Step S617) the following process is executed. In other words, the authenticating unit 22h notifies the image capturing apparatus 21 of an image capturing ending instruction (Step S618), outputs the authentication result of successful authentication or authentication failure to the image capturing apparatus 21 and to the unlocking device not illustrated (Step S619), and ends the process.

Advantageous Effects Achieved by Second Embodiment

As described above, the face authentication system 20 according to the second embodiment turns OFF the illumination unit 11b and captures OFF images before and after N pieces of ON images are captured, in the same manner as in the first embodiment described above. Therefore, the face authentication system 20 according to the second embodiment can reduce the frequency at which the illumination is switched from ON to OFF or from OFF to ON, and the frequency of and the time for null write can be reduced. As a result, idle time for capturing images can be reduced. Therefore, in the face authentication system 20 according to the second embodiment as well, the image capturing time can be reduced.

Furthermore, in the face authentication system 20 according to the second embodiment, the image capturing apparatus 21 performs the process of computing the difference between an OFF image and an ON image, the process of integrating the difference images, and the like. Therefore, in the face authentication system 20 according to the second embodiment, only one piece of integrated image can be transferred from the image capturing apparatus 21 to the authentication apparatus 22, without transferring the N pieces of OFF images and the N pieces of ON images. Therefore, the communication traffic between the image capturing apparatus 21 and the authentication apparatus 22 can be reduced. Hence, for example, a communication load on a network connecting the image capturing apparatus 21 and the authentication apparatus 22 can be reduced. As a result, a high speed authenticating process can be realized.

Furthermore, in the face authentication system 20 according to the second embodiment, because the image capturing time is reduced, extension in the image capturing time can be suppressed even when used is an image sensor capturing images at a low rate and a long interval. For this reason, because an inexpensive image sensor can be used, costs can be reduced.

Furthermore, because the ON images are captured continuously at the center of the image capturing sequence, the influence of the variations in the external light and the subject can be reduced. This is because an ON image has higher luminance, an ON image is more influenced by such variations than an OFF image. By capturing the ON images continuously at the center of the image capturing sequence, the influence of such variations can be further reduced.

Explained in the second embodiment is an example in which the face authentication system 20 is used in controlling an entry and exit of user so that the user is permitted or not permitted to make an entry or exit depending on the authentication result output from the authentication apparatus 22. Alternatively, the face authentication system 20 may be used for other purposes. For example, the face authentication system 20 may also be used in login management in which a login to an information processing apparatus such as a personal computer is permitted or not permitted depending on the authentication result.

[c] Third Embodiment

Explained in the second embodiment is an example in which the authentication apparatus 22 is caused to execute a face authentication using an integrated image. However, an

21

integrated image may also be used in determining the material of an object, without limitation to a face authentication. Therefore, explained in a third embodiment of the present invention is an example in which a determination apparatus 32 is caused to determine the material of an object using an integrated image.

Configuration of Material Determining System

FIG. 13 is a block diagram illustrating functional configurations of apparatuses included in a material determining system according to the third embodiment. A material determining system 30 illustrated in FIG. 13 determines the material of an object by comparing an integrated image of the object generated using an illumination unit 31bA with an integrated image of the object generated using an illumination unit 31bB. In the following description of the third embodiment, as an example, it is assumed that the material determination is used in determining if an object is made of a material α or a material β .

As illustrated in FIG. 13, this material determining system 30 includes an image capturing apparatus 31 and the determination apparatus 32. Among these apparatuses, the image capturing apparatus 31 is installed at a position enabling an object whose material is to be determined to be placed in the angle of view of the image capturing apparatus 31 so that images of the object whose material is to be determined can be captured, as an example. The determination apparatus 32 may be implemented as a server connected to a plurality of image capturing apparatuses 31, as an example. Alternatively, a function for executing the material determination may be incorporated into the image capturing apparatus 31 so that the material determination is performed on standalone basis.

Configuration of Image Capturing Apparatus 31

To begin with, the functional configuration of the image capturing apparatus 31 according to the third embodiment will be explained. The image capturing apparatus 31 illustrated in FIG. 13 includes the following functional units, instead of the sensor unit 21a, the illumination unit 21b, the image sensor 21c, the communicating unit 21d, the image storage unit 21e, the image capturing control unit 21f, the determining unit 21g, the computing unit 21h, and the integrating unit 21j included in the image capturing apparatus 21 illustrated in FIG. 10. In other words, the image capturing apparatus 31 includes a sensor unit 31a, the illumination unit 31bA, the illumination unit 31bB, an image sensor 31c, a communicating unit 31d, an image storage unit 31e, an image capturing control unit 31f, a determining unit 31g, a computing unit 31h, and an integrating unit 31j.

The sensor unit 31a, an illumination unit 31b, the image sensor 31c, the communicating unit 31d, the image storage unit 31e, the image capturing control unit 31f, the determining unit 31g, the computing unit 31h, and the integrating unit 31j have basic functions that are the same as those of the respective functional units illustrated in FIG. 10. Therefore, only the differences are explained hereunder.

Among these units, the sensor unit 31a is different from the sensor unit 21a illustrated in FIG. 10 in that the sensor unit 31a detects an object whose material is to be determined. Therefore, the sensor unit 31a monitors an area in which the object whose material is to be determined is installed, e.g., a radius of 1 meter, from the image capturing apparatus 31. When the sensor unit 31a detects any object in such an installation area, the sensor unit 31a notifies the image capturing control unit 31f, which will be described later, that an object is installed in the installation area.

The illumination unit 31bA is different from the illumination unit 21b illustrated in FIG. 10 in that the illumination unit 31bA illuminates the object whose material is to be deter-

22

mined. Therefore, the illumination unit 31bA is installed at a position for illuminating the central portion of a region to be determined of the object that is installed in the installation area detected by the sensor unit 31a, for example. When the illumination unit 31bA has directivity, the illumination unit 31bA may be provided with a mechanical unit for allowing the direction to which the illuminating light is output to be adjusted depending on the position of an object in the installation area. In the description hereunder, it is assumed that the illumination unit 31bA uses an illumination A with a wavelength at λ_A as a light source.

The illumination unit 31bB is different from the illumination unit 31bA in that the wavelength of the light source is longer than that of the illumination unit 31bA. In the description below, it is assumed that the illumination unit 31bB uses an illumination B having a wavelength at λ_B is that is longer than λ_A as a light source.

The image sensor 31c is different from the image sensor 21c illustrated in FIG. 10 in that the image sensor 31c is installed at a position where the object in the installation area is allowed to be imaged on the image sensor 21c via a lens not illustrated. The image sensor 31c may also include a mechanical unit for adjusting the angular field of the image capturing apparatus 31 depending on the position of the object in the installation area so that the region to be determined of the object can be imaged on the image sensor 31c. The image capturing control unit 31f, which will be described later, stores the images captured by the image sensor 31c in the image storage unit 31e.

The communicating unit 31d is different from the communicating unit 21d illustrated in FIG. 10 in that the communicating unit 31d transmits and receives different types of data to and from other apparatuses including the determination apparatus 32. For example, the communicating unit 31d transfers an integrated image for the illumination unit 31bA and an integrated image for the illumination unit 31bB both of which are generated by the integrating unit 31j to be described later to the determination apparatus 32.

The image storage unit 31e stores therein different types of data from those stored in the image storage unit 21e illustrated in FIG. 10. As described above, in the third embodiment, the image capturing apparatus 31 captures the OFF images and the ON images using the illumination units 31bA and 31bB, computes difference images, and generates an integrated image. Therefore, the image storage unit 31e stores therein original images such as OFF images and ON images for the illumination units 31bA and 31bB acquired from the image sensor 31c, difference images, and an integrated image.

The image capturing control unit 31f is different from the image capturing control unit 21f illustrated in FIG. 10 in that image capturing control unit 31f captures not only ON images with the illumination unit 31bA but also ON images with the illumination unit 31bB. As an example, the image capturing control unit 31f turns ON the illumination unit 31bA and turns OFF the illumination unit 31bB, and captures N pieces of ON images with the illumination unit 31bA before and after turning OFF the illumination unit 31bA, turning ON the illumination unit 31bB, and capturing N pieces of ON images with the illumination unit 31bB. Furthermore, the image capturing control unit 31f also turns OFF the illumination unit 31bA and the illumination unit 31bB, and captures 2*N pieces of OFF images before and after turning ON the illumination unit 31bA, turning OFF the illumination unit 31bB, and capturing N pieces of ON images with the illumination unit 31bA. For example, after turning OFF the illumination unit 31bA and the illumination unit 31bB and capturing N pieces of OFF images, the image capturing control unit 31f turns ON the

23

illumination unit **31bA** and captures N/2 pieces of ON images with the illumination unit **31bA**. The image capturing control unit **31f** then turns OFF the illumination unit **31bA** and turns ON the illumination unit **31bB**, and captures N pieces of ON images with the illumination unit **31bB**. The image capturing control unit **31f** then turns OFF the illumination unit **31bB**, turns ON the illumination unit **31bA**, and captures N/2 pieces of ON images with the illumination unit **31bA**, and then turns OFF the illumination unit **31bA** and the illumination unit **31bB** and captures N pieces of OFF images.

FIG. **14** is a schematic of an example of the image capturing sequence. Illustrated as an example in FIG. **14** is an image capturing sequence of when the divisor N is "4". As illustrated in FIG. **14**, the image capturing control unit **31f** keeps the illumination unit **31bA** and the illumination unit **31bB** OFF for a period from time H0 to time H4, and closes the shutter temporarily at time H1, time H2, and time H3. In this manner, the image capturing control unit **31f** stores an OFF image aA1 acquired through the exposure over a period from "H0 to H1", an OFF image aA2 acquired through the exposure over a period from "H1 to H2", an OFF image aB1 acquired through the exposure over a period from "H2 to H3", and an OFF image aB2 acquired through the exposure over a period from "H3 to H4" in the image storage unit **31e** in the order described herein. The image capturing control unit **31f** then switches the illumination unit **31bA** from OFF to ON at time H4. At this time, the image capturing control unit **31f** performs null write to the image storage unit **31e** for an image acquired through the exposure over a period "H4 to H5", assuming that switching from OFF to ON takes time from time H4 to time H5.

The image capturing control unit **31f** keeps the illumination unit **31bA** ON for a period from time H5 to time H7, closes the shutter temporarily at time H6. As a result, an ON image bA1 acquired through the exposure over a period from "H5 to H6" and an ON image bA2 acquired through the exposure over a period from "H6 to H7" are stored in the image storage unit **31e** in the order described herein. The image capturing control unit **31f** then switches the illumination unit **31bA** from ON to OFF at time H7, and switches the illumination unit B from OFF to ON. The image capturing control unit **31f** then performs null write to the image storage unit **31e** for an image acquired through the exposure over a period "H7 to H8". The image capturing control unit **31f** then keeps the illumination unit **31bB** ON for a period from time H8 to time H12, and closes the shutter temporarily at time H9, time H10, and time H11. In this manner, the image capturing control unit **31f** causes the image storage unit **31e** to store therein an ON image bB1 acquired through the exposure over a period from "H8 to H9", an ON image bB2 acquired through the exposure over a period from "H9 to H10", an ON image bB3 acquired through the exposure over a period from "H10 to H11", and an ON image bB4 acquired through the exposure over a period from "H11 to H12" in the order described herein. The image capturing control unit **31f** then switches the illumination unit **31bA** from OFF to ON, and switches the illumination unit B from ON to OFF at time H12. The image capturing control unit **31f** then performs null write to the image storage unit **31e** for an image acquired through the exposure over a period "H12 to H13".

The image capturing control unit **31f** then keeps the illumination unit **31bA** ON for a period from time H13 to time H15, and closes the shutter temporarily at time H14. As a result, an ON image bA3 acquired through the exposure over a period from "H13 to H14" and an ON image bA4 acquired through the exposure over a period from "H14 to H15" are stored in the image storage unit **31e** in the order described

24

herein. The image capturing control unit **31f** then switches the illumination unit **31bA** from ON to OFF at time H15. The image capturing control unit **31f** then performs null write to the image storage unit **31e** for an image acquired through the exposure over a period "H15 to H16". The image capturing control unit **31f** then keeps the illumination unit **31bA** and the illumination unit **31bB** OFF for a period from time H16 to time H20, and closes the shutter temporarily at time H17, time H18, and time H19. In this manner, the image capturing control unit **31f** causes the image storage unit **31e** to store therein an OFF image aB3 acquired through the exposure over a period from "H16 to H17", an OFF image aB4 acquired through the exposure over a period from "H17 to H18", an OFF image aA3 acquired through the exposure over a period from "H18 to H19", and an OFF image aA4 acquired through the exposure over a period from "H19 to H20" in the order described herein.

The determining unit **31g** is different from the determining unit **21g** illustrated in FIG. **10** in that the determining unit **31g** determines the divisor using information in which the intensity of the external light is associated with a divisor. As a possible implementation, the determining unit **31g** determines the divisor N using information in which an output current is associated with a divisor. This information serves as an index for the intensity of external light, and is stored in an information storage unit **31m** which is to be described later. FIG. **15** is a schematic of an example of information in which an output current is associated with a divisor. For example, when an output current measured with a measuring unit **31k** to be described later is 35 milliamperes, the determining unit **31g** determines "4" as the divisor N. In determining the divisor N, in order to suppress saturation, the determining unit **31g** determines the divisor N using an illumination whose optimal exposure time is the longest. For example, when the optimal exposure time with the light from the illumination unit **31bB** is longer than that with the illumination unit **31bA**, the determining unit **31g** causes the measuring unit **31k** to measure the output current using the light of the illumination unit **31bB**, and determines the divisor N. An image capturing instruction containing the divisor N thus determined and the exposure time E is then output to the image capturing control unit **31f**.

The computing unit **31h** is different from the computing unit **21h** illustrated in FIG. **10** in that the computing unit **31h** computes difference images for each of the illumination unit **31bA** and the illumination unit **31bB**. Therefore, in the example illustrated in FIG. **14**, the computing unit **31h** establishes four pairs by pairing the OFF image aA1 and the ON image bA1, pairing the OFF image aA2 and the ON image bA2, pairing the OFF image aA3 and the ON image bA3, and pairing the OFF image aA4 and the ON image bA4. The computing unit **31h** then computes a difference image A1 for the illumination unit **31bA** by computing pixel value differences between the pixels in the OFF image aA1 and those in the ON image bA1. In the same manner, the computing unit **31h** computes a difference image A2 from the OFF image aA2 and the ON image bA2, computes a difference image A3 from the OFF image aA3 and the ON image bA3, and computes a difference image A4 from the OFF image aA4 and the ON image bA4.

The computing unit **31h** also establishes four pairs by pairing the OFF image aB1 and the ON image bB1, pairing the OFF image aB2 and the ON image bB2, pairing the OFF image aB3 and the ON image bB3, and pairing the OFF image aB4 and the ON image bB4. The computing unit **31h** computes a difference image B1 for the illumination unit **31bB** by computing pixel value differences between the pixels in the

25

OFF image aB1 and those in the ON image bB1. In the same manner, the computing unit 31h computes a difference image B2 from the OFF image aB2 and the ON image b2, computes a difference image B3 from the OFF image aB3 and the ON image bB3, and computes a difference image B4 from the OFF image aB4 and the ON image bB4. In this manner, the computing unit 31h computes N pieces of difference images for the illumination unit 31bA and N pieces of difference images for the illumination unit 31bB. The computing unit 31h then stores N pieces of difference images for the illumination unit 31bA and those for the illumination unit 31bB in an image storage unit 31e.

The integrating unit 31j is different from the integrating unit 31j illustrated in FIG. 10 in that the integrating unit 31j generates an integrated image for each of the illumination unit 31bA and the illumination unit 31bB.

Furthermore, the image capturing apparatus 31 also includes the measuring unit 31k and the information storage unit 31m. Among these units, the measuring unit 31k is a processing unit that measures the intensity of external light. As a possible implementation, the measuring unit 31k measures an output current acquired by the generation of an electromotive force resulting from the photovoltaic effect achieved when the measuring unit 31k is illuminated with the light from the illumination, as an index of the external light intensity. The optimal exposure time differs depending on the illumination, because the light intensity of the illumination and the sensitivity of the image sensor vary depending on the wavelength of the illumination. Furthermore, saturation is more likely to be produced from an illumination with a long optimal exposure time than one with a short optimal exposure time. Therefore, in order to suppress saturation, the measuring unit 31k sets the wavelength of the light to be measured to the wavelength of the light whose optimal exposure time is the longest. An example of a possible implementation of the measuring unit 31k includes a detector such as a photodiode or a phototransistor.

The information storage unit 31m is a storage device storing therein information in which an intensity of the external light is associated with a divisor. As an example, the information storage unit 31m stores therein information in which an output current measured with the measuring unit 31k is associated with a divisor in advance. As an example, to the information in which an intensity of the external light is associated with a divisor, values acquired through experiments or the like are set in advance. In the example illustrated in FIG. 15, this information is information having a table format in which a divisor corresponding to an output current range is set in the same row as the output current range. As another example, the information storage unit 31m is accessed, when an output current is measured with the measuring unit 31k, to read the information of the divisor corresponding to the output current thus measured.

Configuration of Determination Apparatus 32

A functional configuration of the determination apparatus 32 according to the third embodiment will now be explained. The determination apparatus 32 illustrated in FIG. 13 includes a communicating unit 32a and a storage unit 32b, instead of the communicating unit 22a, and the storage unit 22b included in the authentication apparatus 22 illustrated in FIG. 10.

Because the communicating unit 32a and the storage unit 32b have basic functions that are the same as those of the respective functional units illustrated in FIG. 10, only the differences are explained hereunder.

Among these units, the communicating unit 32a transmits and receives different types of data to and from other appar-

26

atuses including the image capturing apparatus 31, from those transmitted and received by the communicating unit 22a illustrated in FIG. 10. For example, the communicating unit 32a receives an integrated image for the illumination unit 31bA and an integrated image for the illumination unit 31bB from the image capturing apparatus 31.

The storage unit 32b stores therein different types of data from those stored in the storage unit 22b illustrated in FIG. 10. As described earlier, in the third embodiment, the image capturing apparatus 31 transfers an integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB to the determination apparatus 32. Therefore, as an example, when the integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB are received from the image capturing apparatus 31, the storage unit 32b stores therein the integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB. As another example, when a material determination is performed, the storage unit 32b is accessed by a determination unit 32c, which will be described later, making a reference to the integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB.

The determination apparatus 32 further includes the determination unit 32c. The determination unit 32c is a processing unit that determines the material of an object, using the integrated images generated by the image capturing apparatus 31. As a possible implementation, the determination unit 32c determines the material of an object by computing luminance ratio between the luminance in an image A that is an integrated image for the illumination unit 31bA and that in an image B that is an integrated image for the illumination unit 31bB. FIG. 16 is a graph illustrating an example of a relation between a wavelength and reflectance of different materials. As illustrated in FIG. 16, reflectance of a material differs depending on the wavelength of the illuminating light. Therefore, the material of an object can be determined by comparing the luminance in an image captured when the object is illuminated with the light from the illumination unit 31bA at a wavelength λ_A and another image captured when the object is illuminated with the illumination unit 31bB at a wavelength λ_B . For example, the determination unit 32c sets a determined area D to the integrated images generated by the image capturing apparatus 31. The determination unit 32c then computes $R(x, y) = IA(x, y)/IB(x, y)$, which is the ratio between luminance $IA(x, y)$ at coordinates (x, y) in the image A and luminance $IB(x, y)$ at the coordinates (x, y) in the image B, for every point $P(x, y)$ in the determined area D. The determination unit 32c then determines if the luminance ratio $R(x, y)$ between the image A and the image B thus computed is lower than the predetermined threshold. If $R(x, y)$ is lower than the predetermined threshold, the determination unit 32c determines that the object is made of material α . If $R(x, y)$ is equal to or higher than the predetermined threshold, the determination unit 32c determines that the object is made of material β .

Sequence of Processes

The sequence of processes performed by the material determining system 30 according to the third embodiment will now be explained. In this section, (1) a determining process performed by the material determining system 30 will be explained to begin with, and (2) a divisor determining process and (3) an image capturing process included in the determining process will then be explained in detail.

(1) Determining Process

FIG. 17 is a flowchart illustrating the determining process according to the third embodiment. The determining process is initiated when the sensor unit 31a detects an object in the

27

installation area. As illustrated in FIG. 17, when the sensor unit 31a detects an object in the installation area (Step S801), the determining unit 31g executes the “divisor determining process” for determining the divisor N by which the exposure time E is divided (Step S802).

The image capturing control unit 31f captures N pieces of OFF images, N/2 pieces of ON images with the illumination unit 31bA, and N pieces of ON images with the illumination unit 31bB in the order described herein, based on the image capturing instruction containing image capturing parameters including the divisor N determined by the determining unit 31g. The image capturing control unit 31f then captures N/2 pieces of ON images with the illumination unit 31bA and N pieces of OFF images in the order described herein. In this manner, the image capturing control unit 31f performs the “image capturing process” in which 2*N pieces of OFF images, N pieces of ON images with the illumination unit 31bA, and N pieces of ON images with the illumination unit 31bB are captured (Step S803).

The computing unit 31h then determines N pairs of an OFF image and an ON image with the illumination unit 31bA, and N pairs of an OFF image and an ON image with the illumination unit 31bB. The computing unit 31h then computes N pieces of difference images from the respective pairs of an OFF image and an ON image for each of the illumination unit 31bA and the illumination unit 31bB (Step S804). The computing unit 31h stores the N pieces of difference images for each of the illumination unit 31bA and the illumination unit 31bB computed at Step S804 in the image storage unit 31e (Step S805).

The integrating unit 31j then acquires the sum of the pixel values across the N pieces of difference images for each of the illumination unit 31bA and the illumination unit 31b, stored in the image storage unit 31e. In this manner, the integrating unit 31j generates a single piece of integrated image for the illumination unit 31bA and a single piece of integrated image for the illumination unit 31bB, from the N pieces of difference images for the illumination unit 31bA and the N pieces of difference images for the illumination unit 31bB, respectively (Step S806). The integrating unit 31j then stores the integrated images generated at Step S806 in the image storage unit 31e (Step S807). The image capturing apparatus 31 transfers the integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB to the determination apparatus 32 via the communicating unit 31d (Step S808).

The determination apparatus 32 stores the integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB in the storage unit 32b (Step S809). The determination unit 32c then computes a luminance ratio R from the integrated image for the illumination unit 31bA and the integrated image for the illumination unit 31bB stored at Step S809 in the storage unit 32b (Step S810).

If the luminance ratio R is equal to or higher than the predetermined threshold (Yes at Step S811), the determination unit 32c determines that the object is made of a material β (Step S812), and the process is ended. If the luminance ratio R is lower than the predetermined threshold (No at Step S811), the determination unit 32c determines that the object is made of a material α (Step S813), and the process is ended.

(2) Divisor Determining Process

FIG. 18 is a flowchart illustrating a divisor determining process according to the third embodiment. This process is initiated when the process at Step S801 is executed in the determining process illustrated in FIG. 17, in other words, when the sensor unit 31a detects an object.

28

As illustrated in FIG. 18, the measuring unit 31k measures the output current (Step S901). The determining unit 31g then determines the divisor N from the output current measured with the measuring unit by referring to the associating information that is the information in which an output current is associated with a divisor (Step S902). The determining unit 31g then outputs an image capturing instruction containing the divisor N thus determined to the image capturing control unit 31f (Step S903), and the process is ended.

(3) Image Capturing Process

FIG. 19 is a flowchart illustrating the image capturing process according to the third embodiment. This image capturing process is initiated when an image capturing instruction is received from the determining unit 31g.

As illustrated in FIG. 19, the image capturing control unit 31f computes the unit exposure time E' representing an exposure time for a single piece of image, by dividing the exposure time E by the divisor N (Step S1001).

The image capturing control unit 31f then turns OFF the illumination unit 31bA and the illumination unit 31bB, and captures N pieces of OFF images (Step S1002). The image capturing control unit 31f then turns ON the illumination unit 31bA, keeps the illumination unit 31bB OFF, and captures N/2 pieces of ON images with the illumination unit 31bA (Step S1003). The image capturing control unit 31f then turns OFF the illumination unit 31bA, turns ON the illumination unit 31bB, and captures N pieces of ON images with the illumination unit 31bB (Step S1004). The image capturing control unit 31f then turns ON the illumination unit 31bA, turns OFF the illumination unit 31bB, and captures N/2 pieces of ON images with the illumination unit 31bA (Step S1005). The image capturing control unit 31f then turns OFF the illumination unit 31bA and the illumination unit 31bB, and captures N pieces of OFF images (Step S1006).

Finally, the image capturing control unit 31f stores the N pieces of OFF images, the N pieces of ON images with the illumination unit 31bA, and the N pieces of ON images with the illumination unit 31bB acquired through the process at Step S1002 to Step S1006 in the image storage unit 31e (Step S1007), and the process is ended.

Advantageous Effects Achieved by Third Embodiment

As described above, the material determining system 30 according to the third embodiment captures OFF images before and after capturing the ON images. Because the material determining system 30 according to the third embodiment can reduce the frequency at which the illumination is switched from ON to OFF or from OFF to ON, the frequency of and the time for null write can be reduced. As a result, idle time for capturing images can be reduced. Hence, the material determining system 30 according to the third embodiment can reduce the image capturing time.

Furthermore, the material determining system 30 according to the third embodiment determines the divisor using an apparatus for measuring an output current and information in which an output current is associated with a divisor. Therefore, with the material determining system 30 according to the third embodiment, because the process for determining the divisor can be simplified, the image capturing time can be reduced. As an example, because capturing of ON images for determining the divisor and the computation of the external light evaluation value can be omitted, the image capturing time can be reduced. As another example, because when the external light is lower than the predetermined threshold, the process of computing the difference images and the process of generating the integrated image can be omitted by setting the divisor to zero, the image capturing time can be reduced.

29

Furthermore, in the material determining system 30 according to the third embodiment, because the image capturing time is reduced, extension in the image capturing time can be suppressed, even when used is an image sensor capturing images at a low rate and a long interval. Because an inexpensive image sensor can be used, costs can be reduced.

Furthermore, because the ON images are captured continuously at the center of the image capturing sequence, the influence of the variations in the external light and the subject can be reduced. This is because an ON image has higher luminance, an ON image is more influenced by such variations than an OFF image. By capturing the ON images continuously at the center of the image capturing sequence, the influence of such variations can be further reduced.

Furthermore, because the material determining system 30 according to the third embodiment determines the divisor based on an illumination whose optimal exposure time is the longest, saturation can be suppressed. Therefore, the determination accuracy can be improved.

Furthermore, in the material determining system 30 according to the third embodiment, capturing of images with the illumination whose optimal exposure time is the longest is positioned at the center of the image capturing sequence. In the material determining system 30 according to the third embodiment, because capturing of images with the largest amount of information is positioned at the center of the image capturing sequence, the influence of variations such as positional changes in the object or changes in the external light intensity can be reduced.

[d] Fourth Embodiment

Some embodiments related to the apparatuses according to the present invention are described so far, but the present invention may be implemented in various forms other than those disclosed in the embodiments. Other embodiments included in the present invention will now be explained.

Types of Subject to be Authenticated

Explained in the second embodiment is an example in which a face authentication is performed as a biometric authentication. However, the authenticated region is not limited to a face, but other biometric information such as a fingerprint or a palm vein may be used. For example, in the palm vein authentication, a palm that is the subject is irradiated with an illumination having a high transmittance to a human body, and an image capturing apparatus is caused to capture a reflected light. The person is then authenticated using a subdermal vein pattern captured by the image capturing apparatus as characteristics to be authenticated. Because a palm vein authentication uses a vein pattern that is usually invisible to human eyes in the authentication, the risk of leakage of characteristics to be authenticated is low. Therefore, such a palm vein authentication can be used as a personal authentication technology mainly in high-security fields, such as in a bank automatic tellers machine (ATM). Furthermore, because a palm vein authentication is a non-contact authentication not allowing the subject to touch the sensor, the user is forced to hold his/her hand over the sensor for a longer time when the image capturing time is extended. Therefore, the convenience can be improved by reducing the image capturing time.

Parallel Processing of Image Generation

Used in the example explained in the second embodiment and the third embodiment is an approach in which the OFF images and ON images, the difference images, and the integrated image are generated sequentially. However, an approach in which these images are generated in parallel may also be used. For example, the process of generating the difference image may be initiated once a single piece of OFF

30

image and a single piece of ON image are generated, and the process of integrating the difference images for generating an integrated image may be initiated sequentially every time two pieces of difference images are generated. In this manner, generation of the OFF image and the ON image, generation of the difference image, and generation of the integrated image can be performed in parallel, without waiting for each of these processes of image generation to be completed. In this manner, the image capturing time can be reduced.

Exemplary Alternative of Divisor Determining Process

Used in the example explained in the first to the third embodiments is an approach in which the divisor is determined by capturing ON images for determining the divisor, in addition to the ON images used in computing difference images. However, the ON images used in computing the difference images may also be used in determining the divisor. For example, the N pieces of ON images captured after the N/2 pieces of OFF images are captured may be used as the ON images for determining the divisor.

FIG. 20 is a flowchart illustrating an example of such a divisor determining process. Explained hereunder is an example the second embodiment is applied with an approach in which the divisor is determined using the ON images that are used in computing difference images. The divisor determining process illustrated in FIG. 20 is initiated when a user is detected in the pass-through area of the gate, as illustrated in FIG. 12. As illustrated in FIG. 20, the determining unit 21g sets the initial value N_0 to the divisor N (Step S701). The determining unit 21g then sets the unit exposure time E' to E/N that is computed from the exposure time E and the divisor N (Step S702).

The determining unit 21g then causes the image capturing control unit 21f to capture N/2 pieces of OFF images based on the unit exposure time E' (Step S703). The determining unit 21g then causes the image capturing control unit 21f to capture N pieces of ON images (Step S704). The determining unit 21g computes the external light evaluation value E_x from the ON images captured at Step S704 (Step S705). The determining unit 21g determines if the external light evaluation value E_x is lower than predetermined threshold Th (Step S706).

If the external light evaluation value E_x is equal to or higher than the predetermined threshold Th (No at Step S706), the determining unit 21g updates the divisor N to a value larger than the previous value, e.g., a value twice the previous divisor (Step S707). The system control then goes to Step S702, and the determining unit 21g repeats the process of updating the divisor, setting a unit exposure time E' , capturing OFF images, capturing ON images, and computing the external light evaluation value E_x , until the external light evaluation value E_x reaches a value lower than the threshold Th . If the external light evaluation value E_x is lower than predetermined threshold Th (Yes at Step S706), the determining unit 21g outputs the divisor N used at Step S701 or at Step S707 to the image capturing control unit 21f (Step S708), and the process is ended. Once the divisor determining process is completed, the image capturing apparatus 21 performs the process at Step S605 and thereafter illustrated in FIG. 12.

At this time, because the divisor is determined using the N pieces of ON images captured by the image capturing control unit 21f used in computing difference images, capturing of ON images for determining the divisor, which are images not used in computing difference images, is not required. Therefore, the number of times the ON images are captured is reduced. Thus, the image capturing time can be reduced.

Explained above is an example in which the second embodiment is applied with an approach in which the divisor

31

is determined using the ON images used in computing difference images. However, such an approach may be applied to the first embodiment or the third embodiment, without limitation to the second embodiment.

Continuous Capturing

Used in the example explained in the first to the third embodiments is an approach in which the N pieces of OFF images and the N pieces of ON images are captured. However, the N pieces of OFF images and the N pieces of ON images may be captured continuously. FIG. 21 is a schematic of an example of such an image capturing sequence. Illustrated in FIG. 21 is an example of an image capturing sequence in which images are captured repeatedly when the divisor N is "4". Explained hereunder is an example in which the continuous capturing is applied to the second embodiment. As illustrated in FIG. 21, the image capturing control unit 21f keeps the illumination unit 21b OFF during a period from time M0 to time M2, and closes the shutter temporarily at time M1. The image capturing control unit 21f then causes the image storage unit 21e to store therein an OFF image c1 acquired through the exposure over a period from "M0 to M1", and causes the image storage unit 21e to store therein an OFF image c2 acquired through the exposure over a period "M1 to M2". The image capturing control unit 21f then switches the illumination unit 21b from OFF to ON at time M2. At this time, certain time is taken to complete switching from OFF to ON. Therefore, assuming that switching from OFF to ON takes time from time M2 to time M3, the image capturing control unit 21f performs null write to the image storage unit 21e for an image acquired through the exposure over a period "M2 to M3". Null is thus stored because any image acquired before switching to ON or OFF is completed is not used in the authentication.

The image capturing control unit 21f then keeps the illumination unit ON for a period from time M3 to time M7, and closes the shutter temporarily at time M4, time M5, and time M6. As a result, the ON image d1 acquired through the exposure over a period from "M3 to M4", the ON image d2 acquired through the exposure over a period from "M4 to M5", the ON image d3 acquired through the exposure over a period from "M5 to M6", and the ON image d4 acquired through the exposure over a period from "M6 to M7" are stored in the image storage unit 21e in the order described herein. The image capturing control unit 21f switches the illumination unit 21b from ON to OFF at time M7. The image capturing control unit 21f performs null write to the image storage unit 21e for an image acquired through the exposure over a period from "M7 to M8". The image capturing control unit 21f keeps the illumination unit 21b OFF for a period from time M8 to time M10, and closes the shutter temporarily at time M9 and time M10. After causing the image storage unit 21e to read an OFF image c3 acquired through the exposure over a period "M8 to M9", the image capturing control unit 21f causes the image storage unit 21e to store therein an OFF image c4 acquired through the exposure over a period "M9 to M10". This process is repeated until an image capturing ending instruction is received. Once N pieces of OFF images and N pieces of ON images are stored in the image storage unit 21e, the image capturing control unit 21f instructs the computing unit 21h, which will be described later, to compute difference images.

In the example explained above, the continuous capturing is applied to the second embodiment. However, the continuous capturing may be applied to the first embodiment or the third embodiment, without limitation to the second embodiment.

32

In this example, if it is determined that an OFF images used in computing the previous difference image or to be used in computing the subsequent difference image is captured under similar conditions to those under which the ON image to be used in computing the current difference image is captured than those under which the OFF image to be used in computing the current difference image is captured, the computing unit may compute the current difference image using the OFF image used in computing the previous difference image or to be used in computing the subsequent difference image.

For example, to explain using the example illustrated in FIG. 21, when the difference images are to be computed using the ON images d5 to d8, the computing unit may compute the difference images by pairing these ON images with the OFF images c3 to c6 (the alternative 1 in FIG. 21), with the OFF images c4 to c7 (the alternative 2 in FIG. 21), with the OFF images c5 to c8 (the alternative 3 in FIG. 21), or with the OFF images c6 to c9 (the alternative 4 in FIG. 21). Specifically, for example, for the alternative 2 in FIG. 21, the computing unit establishes four pairs by pairing the OFF image c4 and the ON image d5, pairing the OFF image c5 and the ON image d6, pairing the OFF image c6 and the ON image d7, and pairing the OFF image c7 and the ON image d8. The computing unit then computes a difference image cd1 by computing pixel value differences between the pixels in the OFF image c4 and those in the ON image d5. In the same manner, the computing unit computes a difference image cd2 from the OFF image c5 and the ON image d6, computes a difference image cd3 from the OFF image c6 and the ON image d7, and computes a difference image cd4 from the OFF image c7 and the ON image d8. In this manner, by pairing an ON image with an OFF image used in computing the previous difference image or an OFF image to be used in computing the subsequent difference image, an ON image can be paired with an OFF image captured under similar conditions as those under which the ON image is captured. In this manner, the influence of positional changes in the subject or changes in the external light intensity can be reduced.

Material Determination Using Illumination with Different Distribution Profile

Explained in the third embodiment is an example in which illuminations at different wavelengths are used. Alternatively, an illumination with a different distribution profile may be used. For example, an illumination provided with a lens may be used so that the subject is irradiated with a spot light converged by the lens. Use of a spot light for irradiating the subject enables the distance to the subject to be measured. Therefore, the determination accuracy can be improved.

Image Capturing Program

The various processes explained in the embodiments may be realized by causing a computer such as a personal computer or a workstation to execute a computer program prepared in advance. Explained now with reference to FIG. 22 is an example in which a computer executing an image capturing program having the same functions as those described in the embodiments.

FIG. 22 is a schematic for explaining an example of a computer for executing an image capturing program according to the first to the third embodiments. As illustrated in FIG. 22, this computer 100 includes an operation unit 110a, a speaker 110b, a camera 110c, a display 120, and a communicating unit 130. The computer 100 also includes a CPU 150, a read-only memory (ROM) 160, a hard-disk drive (HDD) 170, and a random access memory (RAM) 180. These units are connected via a bus 140.

An image capturing program 1708 achieving the same functions as those of the image capturing control unit 11f, the

33

determining unit 12d, the computing unit 12e, the integrating unit 12f, and the authenticating unit 12g described in the first embodiment is stored in advance in the HDD 170, as illustrated in FIG. 22. The functions achieved by the image capturing program 170a may be integrated or separated as appropriate, in the same manner as each of the image capturing control unit 11f, the determining unit 12d, the computing unit 12e, the integrating unit 12f and the authenticating unit 12g illustrated in FIG. 1. Furthermore, the functions achieved by the image capturing program 170a may be integrated or separated as appropriate, in the same manner as the image capturing control unit 21f, the determining unit 21g, the computing unit 21h, the integrating unit 21j, and the authenticating unit 22h illustrated in FIG. 10. Furthermore, the functions achieved by the image capturing program 170a may be integrated or separated as appropriate, in the same manner as the image capturing control unit 31f, the determining unit 31g, the computing unit 31h, the integrating unit 31j, and the determination unit 32c illustrated in FIG. 13. In other words, all data to be stored in the HDD 170 does not always need to be stored in the HDD 170, and only data to be used for the processes may be stored in the HDD 170.

The CPU 150 then reads the image capturing program 170a from the HDD 170, and loads the program onto the RAM 180. In this manner, the image capturing program 170a functions as an image capturing process 180a, as illustrated in FIG. 22. The image capturing process 180a loads various types of data read from the HDD 170 onto an area assigned to the image capturing process 180a on the RAM 180, and executes various processes based on such data thus loaded. The image capturing process 180a includes the processes executed by the image capturing control unit 11f, the determining unit 12d, the computing unit 12e, the integrating unit 12f, and the authenticating unit 12g illustrated in FIG. 1, e.g., the process illustrated in FIG. 7. The image capturing process 180a also includes the process executed by the image capturing control unit 21f, the determining unit 21g, the computing unit 21h, the integrating unit 21j, and the authenticating unit 22h illustrated in FIG. 10, e.g., the process illustrated in FIG. 12. The image capturing process 180a also includes the process executed by the image capturing control unit 31f, the determining unit 31g, the computing unit 31h, the integrating unit 31j, and the determination unit 32c illustrated in FIG. 13, e.g., the process illustrated in FIG. 17. Not all of the processing units that are virtually realized on the CPU 150 do not always need to be operating on the CPU 150, and only the processing units to be used for the process may be virtually realized on the CPU 150.

The image capturing program 170a does not necessarily need to be stored in the HDD 170 or in the ROM 160 in advance. For example, each of these computer programs may be stored in a "portable physical medium" inserted into the computer 100 such as a flexible disk (FD), a compact disk read-only memory (CD-ROM), a digital versatile disk (DVD), a magneto-optical disk, or an integrated circuit (IC) card, and the computer 100 then may acquire each of the computer programs from the portable physical medium, and execute the computer program. Alternatively, each of the computer programs may be stored in another computer or a server connected to the computer 100 over a public circuit, the Internet, a local area network (LAN), or a wide area network (WAN), and the computer 100 may acquire each of the computer programs from the computer or the server, and execute the computer program.

An embodiment of the present invention can reduce an image capturing time.

34

All examples and conditional language recited herein are intended for pedagogical purposes of aiding the reader in understanding the invention and the concepts contributed by the inventor to further the art, and are not to be construed as limitations to such specifically recited examples and conditions, nor does the organization of such examples in the specification relate to a showing of the superiority and inferiority of the invention. Although the embodiments of the present invention have been described in detail, it should be understood that the various changes, substitutions, and alterations could be made hereto without departing from the spirit and scope of the invention.

What is claimed is:

1. An image capturing method executed by an image capturing apparatus including an illumination that illuminates a subject, the image capturing method comprising:

continuously generating, using a processor, one or more

OFF images in which the subject is captured with the illumination turned OFF, for a first number of times;

continuously generating, using the processor, ON images in which the subject is captured with the illumination turned ON, for a second number of times;

continuously generating, using the processor, one or more OFF images in which the subject is captured with the illumination turned OFF, for the first number of times after capturing the ON images;

computing, using the processor, a difference image between each of the generated ON images and an OFF image corresponding to the ON image among the generated OFF images; and

integrating, using the processor, the computed difference images, wherein

the generating includes turning OFF the illumination and capturing N/2 OFF images before and after N ON images are captured,

the N is a divisor by which an exposure time is divided, and the exposure time is a time for which an image sensor is exposed to light that is imaged through a lens.

2. The image capturing method according to claim 1, wherein the second number of times includes double of the first number of times.

3. The image capturing method according to claim 1, wherein, the computing the difference image includes:

determining pairs of an ON image and an OFF image in order of times at which the ON images and the OFF images are generated, and

computing the difference image for each of the pairs of the ON image and the OFF image.

4. The image capturing method according to claim 1, further comprising:

computing, from an ON image, an external light evaluation value representing intensity of external light in the ON image; and

determining the first number of times and the second number of times based on the external light evaluation value.

5. The image capturing method according to claim 1, wherein

the computing the difference image includes computing a current difference image using an OFF image used in computing a previous difference image or an OFF image to be used in computing a subsequent difference image, when it is determined that the OFF image used in computing the previous difference image or the OFF image

35

to be used in computing the subsequent difference image is captured under conditions that the OFF image is more similar to an ON image to be used in computing the current difference image than an OFF image to be used in computing the current difference image.

6. The image capturing method according to claim 1, further comprising determining the first number of times and the second number of times based on a captured image under a condition that a longest exposure time is used, when images are captured under different capturing conditions.

7. The image capturing method according to claim 6, wherein, the determining the first number of times and the second number of times includes determining the first number of times and the second number of times based on the captured image under the condition that the longest exposure time is used, when the capturing conditions include a condition related to a wavelength of the illumination or a distribution profile of the illumination.

8. The image capturing method according to claim 1, wherein the generating the ON images includes, when images are captured under different capturing conditions, generating ON images under a condition that a shorter exposure time is used before and after generating a ON image under a condition that a longest exposure time is used.

9. The image capturing method according to claim 8, wherein, the generating the ON images includes, when the capturing conditions include a condition related to a wavelength of the illumination or a distribution profile of the illumination, generating ON images under the condition that the shorter exposure time is used before and after generating the ON image under the condition that the longest exposure time is used.

10. The image capturing method according to claim 1, further comprising determining the first number of times and the second number of times based on intensity of external light measured with a measuring unit that measures intensity of external light.

11. The image capturing method according to claim 10, wherein, the determining the first number of times and the second number of times includes employing the first number of times and the second number of times corresponding to the intensity of external light measured with the measuring unit from information in which intensities of external light are associated with first numbers of times and second numbers of times.

12. The image capturing method according to claim 1, wherein, the generating the ON image, the generating the OFF image, the computing the difference image, and the integrating the difference images are performed independently.

36

13. An image capturing apparatus comprising:
a processor; and

a memory coupled to the processor, wherein the processor executes a process comprising:

continuously capturing one or more OFF images in which a subject is captured with an illumination illuminating the subject turned OFF, for a first number of times;

continuously capturing ON images in which the subject is captured with the illumination turned ON, for a second number of times after capturing the one or more OFF images;

continuously capturing one or more OFF images in which the subject is captured with the illumination turned OFF, for the first number of times after capturing the ON images;

computing a difference image between each of the captured ON images and an OFF image corresponding to the ON image among the captured OFF images; and

integrating the computed difference images, wherein the capturing includes turning OFF the illumination and capturing N/2 OFF images before and after N ON images are captured,

the N is a divisor by which an exposure time is divided, and the exposure time is a time for which an image sensor is exposed to light that is imaged through a lens.

14. A non-transitory computer readable storage medium having stored therein an image capturing program that causes a computer to execute a process comprising:

continuously capturing one or more OFF images in which a subject is captured with an illumination illuminating the subject turned OFF, for a first number of times;

continuously capturing ON images in which the subject is captured with the illumination turned ON, for a second number of times after capturing the one or more OFF images;

continuously capturing one or more OFF images in which the subject is captured with the illumination turned OFF, for the first number of times after capturing the ON images;

computing a difference image between each of the captured ON images and an OFF image corresponding to the ON image among the captured OFF images; and

integrating the computed difference images, wherein the capturing includes turning OFF the illumination and capturing N/2 OFF images before and after N ON images are captured,

the N is a divisor by which an exposure time is divided, and the exposure time is a time for which an image sensor is exposed to light that is imaged through a lens.
